CHARACTERISTICS OF MUNICIPAL WASTEWATERS, 1971 to 1973

Deirdre J. McDermott

Municipal wastewaters are the major man made source of most pollutants to southern California coastal waters. Hence, it is important to follow fluctuations in the concentrations of various constituents in the final effluents of local treatment plants. It is also of interest to know to what degree these effluents meet the 1972 standards for ocean discharge set by the California Water Resources Control Board.

In the past year, we have reviewed the 1971 73 monitoring data of the five major southern California treatment plants. Using these data, we have estimated the 1972 and 1973 mean yearly concentrations of 28 wastewater constituents or characteristics in the final effluents of these plants; the 1973 values are given in Table 1 (1971 data was presented in the Project's 3 year report.)

Several points of interest can be gleaned from a comparison of the 1971 and 1973 mass emission rates (MER's) for each discharger (Tables 2 and 3):

- On the average, ten of the thirteen MER's for the "general" constituents measured at the Los Angeles County Joint Water Pollution Control Plan (JWPCP) on Palos Verdes Peninsula decreased by 26 percent (range: 15 to 40 percent) since 1971. The exceptions were total phosphate, which remained the same, phenols, which increased by 10 percent and cyanide, which almost tripled.

- Similarly, on the average, MER's of nine of the twelve metals measured decreased by 26 percent (range: 15 40 percent) in this 2 year period at JWPCP. The exceptions were silver, which only decreased by half, and nickel, which increased by 7 percent. Arsenic was not measured in 1971, and the analytical technique for this element has only recently become reliable.

- In 1970, the discharge of DDT wastes by Montrose Chemical Company into the JWPCP system was halted. This resulted in a dramatic decrease of 83 percent in the total DDT mass emission rate since 1971. The MER for total PCB (which apparently enters the system through numerous sources) also decreased by 75 percent.

- In the final effluent of Hyperion's 5 mile outfall, the MER's for nine of the thirteen general constituents decreased by 24 percent (range: 10 to 45 percent). Total suspended solids increased by 6 percent, and both oil/ grease and total phosphate increased by 28 percent. Volatile suspended solids were not measured in 1971, but MER's of these substances decreased by 10 percent from 1972 to 1973.

- MER's for cadmium, copper, nickel, lead, and zinc in Hyperion's 5 mile effluent decreased on the average by 40 percent (range: 25 to 60 percent), while MER's for iron, mercury, and chromium remained about the same.
Arsenic and selenium MER's doubled, and manganese and silver MER's increased by five and twenty times, respectively; however, difficulties with the 1971 analysis may have resulted in erroneously low results, which would largely account for these apparent increases.

- According to the monitoring data, the reported input of total DDT increased by a factor of 4, and total PCB by a factor of 2.5 during these 2 years at the Hyperion 5 mile outfall. Again, we suspect that the 1971 values were too low.

- Orange County Sanitation Districts reported concentrations of only five of the general constituents total suspended solids, volatile suspended solids, 5 day BOD, oil grease, and ammonia nitrogen. All of the MER's for these increased by an average of 20 percent (range: 3 to 35 percent) the flow at this plant has also increased 20 percent in the 2 year period.

- Seven metals were measured at the Orange County plant. The MER's for silver and lead decreased by 25 and 10 percent, respectively. All of the rest increased: cadmium, chromium, copper, and nickel apparently increased by 50 percent or more, and zinc increased by 25 percent. Again, the 1971 measurements of these trace constituents may have been too low.

- The total DDT MER at Orange County apparently increased by 10 percent, while the total PCB MER decreased by 25 percent. Intercalibration experiments are in progress to assist in evaluation of these data.

- All of the trace metals except selenium were measured in the Point Loma Treatment Plant effluent. Despite a 10 per cent increase in flow, the trace metal MER's decreased by an average of 50 percent (range: 20 to 70 percent) except for mercury, which tripled.

- Oxnard measures four of the general constituents total suspended solids, 5 day BOD, oil/grease, and chemical oxygen demand. All of the reported MER's for these parameters increased on an average of 40 percent (range: 15 to 60 percent).

- Despite the predominant decreases in the JWPCP MER's and increases in many of the MER's of the other dischargers, monitoring data indicates that, during 1973, JWPCP discharged 50 percent or more of the total amount of each of the general constituents, 50 percent of the trace metals, 30 percent of the total PCB, and 90 percent of the total DDT released to the ocean by these five wastewater treatment facilities.
The State of California has two sets of concentration limits for various municipal waste parameters. One set consists of concentrations that are not to be exceeded more than 50 percent of the time, the other, concentrations not to be exceeded more than 10 percent of the time. Monthly mean concentrations are available for all dischargers except Ventura County, which only has quarterly data for trace metals and chlorinated hydrocarbons. Based on these data, we performed a review of the major dischargers' capability to meet the State water quality standards in 1973. Table 4 presents the results for the 50 percent standard and Table 5, for the 10 percent requirement. These tables indicate the degree to which each discharger exceeded the concentration limits for any given parameter during the year: The number on the left of the column is the percentage of time* that the limit was exceeded, and the number to the right is the average of the concentrations that exceeded the limit.

In 1973, the 50 percent standards for silver and arsenic were met by all discharges, except that of the Hyperion's 7 mile outfall. On the other hand, none of the dischargers met either standard for total suspended solids, oil/grease, and total chromium.

JWPCP effluent, with its high load of industrial input, did not meet either the 50 percent or 10 percent State requirements for any parameter, except silver. Orange County Sanitation District had a similar problem meeting these standards, except for those for silver and ammonia-nitrogen.

The Hyperion 5 mile effluent exceeded the standards for cyanide, total chromium, mercury, and nickel; the 7 mile effluent exceeded all the standards except for cyanide by at least a factor of 10 and was 1,800 times too high in total chromium. Point Loma effluent also exceeded the standards for three metals total chromium, cadmium, and zinc, and Oxnard effluent exceeded the standards for total chromium and zinc.

The three major dischargers JWPCP, Hyperion, and Orange County all exceeded both limits for total identifiable chlorinated hydrocarbons. (No reliable monitoring data on these constituents is available for Oxnard and Point Loma.)

An extensive examination of the monitoring data from the five dischargers for the 3 year period 1971 to 1973 will be presented in an upcoming technical memorandum.

In considering the municipal wastewater inputs, it is important to realize that a discharger's failure to meet the State standards does not necessarily mean that the discharge is damaging to the marine environment. The standards are based on available scientific information. But, as pointed out throughout this report, there are a number of uncertainties about the fates and effects of each wastewater constituent, and in many cases, it was necessary to set the standard without sufficient information: It is our goal to provide as much of this information as possible.
Table 1.
Average concentrations of general constituents, trace metals, and chlorinated hydrocarbons in the final effluent of municipal waste dischargers, 1973.
