## APPENDIX C - LOGISTIC REGRESSION SUPPLEMENT: <br> DATA, PARAMETER ESTIMATES, AND ADDITIONAL RESULTS

## List of Figures in Appendix C

Figure C. 1 - Screening index logistic regression of all grain sizes using HBml at $\mathrm{Q}_{10}$ vs. $\mathrm{d}_{50}$
.C11
Figure C. 2 - Specific stream power logistic regression of all grain sizes using HBml at $Q_{10}$ vs. $\mathrm{d}_{50} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . C 11 ~$

Figure C. 3 - Dimensionless shear stress logistic regression of all grain sizes using HBm1 at $\mathrm{Q}_{10}$ vs. $\mathrm{d}_{50}$ C12

Figure C. $4-$ Combined screening index logistic regression of $\mathrm{d}_{50}<16 \mathrm{~mm}$ and $\mathrm{d}_{50} \geq 16$ mm using HBm 1 at $\mathrm{Q}_{2}$ vs. $\mathrm{d}_{50}$ C12

Figure C. 5 - Risk of bank failure in poorly and moderately-/well-consolidated materials
$\qquad$
Figure C. 6 - Risk of bank failure in poorly and unconsolidated materials C13

Figure C. 7 - Risk of minor mass wasting in hillslope if channel directly connected to hillslope (i.e., confined)

## List of Tables in Appendix C

Table C. 1 - Summary of logistic regression models of incising/braiding vs. stable singlethread in unconfined valleys: $\mathrm{d}_{50} 0.5-100 \mathrm{~mm}$ C4

Table C. 2 - Summary of logistic regression models of incising/braiding vs. stable singlethread in unconfined valleys: $\mathrm{d}_{50} 0.5-16 \mathrm{~mm}$ C6

Table C. 3 - Summary of logistic regression models of incising/braiding vs. stable single-
thread in unconfined valleys: $d_{50} 16-100 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . C 8 ~$
Table C. 4 - Summary of bank stability models..............................................................C10
Table C. 5 - Incising and braiding data ..........................................................................C15
Table C.6(a) - Bank data: left banks .............................................................................C20
Table C.6(b) - Bank data: right banks ...........................................................................C25
Table C.6(c) - Left bank data: rationale for description of second bank height and angle

Table C.6(d) - Right bank data: rationale for description of second bank height and angle .C36

Table C. 1 - Summary of logistic regression models of incising/braiding vs. stable single-thread in unconfined valleys: $d_{50} 0.5-100 \mathrm{~mm}$

General abbreviations and symbol definitions (excluding units of measure):

| $\mathrm{d}_{50}$ | grain size that 50 percent of the particles are finer than |
| :---: | :---: |
| HBavg | average of all five Hawley-Bledsoe (In review) peak-flow models |
| HBm1 | Hawley-Bledsoe model 1, Q = f (A, P), best performance across all flows during cross validation |
| HBm3 | Hawley-Bledsoe model 3, $\mathrm{Q}=\mathrm{f}\left(\mathrm{Strm}, \mathrm{P}_{224}\right)$, best performance across all flows during final calibration |
| HBm5 | Hawley-Bledsoe model 5, Q = f (Strm, Shp, IP, Sv), best performance during cross validation and final calibration at $Q_{2}$ |
| MI | screening index $=\mathrm{S}_{\mathrm{v}}{ }^{*} \mathrm{Q}_{\mathrm{i}}{ }^{0.5}$ |
| NRCS | NRCS Curve Number method |
| p | probability value |
| $Q_{i}$ | instantaneous peak flow with return interval i years |
| $\mathrm{S}_{\mathrm{v}}$ | valley slope |
| USGS | USGS regional equations (Waananen and Crippen, 1977) |
| $\beta$-parameters | correspond to log-transformed variables (i.e., $\beta_{1}{ }^{*} \ln \left(\mathrm{~d}_{50}\right), \beta_{2} \ln ^{*}\left(\mathrm{~S}_{\mathrm{v}}{ }^{*} \mathrm{Q}_{2}{ }^{0.5}\right)$ ) |
| $\tau_{*}$ | dimensionless shear stress |
| $\omega$ | specific stream power $=\gamma^{*} \mathrm{~S}^{*} \mathrm{Q}_{i} / \mathrm{W}$ |

General abbreviations and symbol definitions (excluding units of measure):

| $\mathrm{d}_{50}$ | grain size that 50 percent of the particles are finer than |
| :---: | :---: |
| HBavg | average of all five Hawley-Bledsoe (In review) peak-flow models |
| HBm1 | Hawley-Bledsoe model 1, Q = f (A, P), best performance across all flows during cross validation |
| HBm3 | Hawley-Bledsoe model 3, $\mathrm{Q}=\mathrm{f}\left(\mathrm{Strm}, \mathrm{P}_{224}\right)$, best performance across all flows during final calibration |
| HBm5 | Hawley-Bledsoe model 5, Q = f (Strm, Shp, IP, Sv), best performance during cross validation and final calibration at $Q_{2}$ |
| MI | screening index $=\mathrm{S}_{\mathrm{v}}{ }^{*} \mathrm{Q}_{\mathrm{i}}{ }^{0.5}$ |
| NRCS | NRCS Curve Number method |
| p | probability value |
| $Q_{i}$ | instantaneous peak flow with return interval i years |
| $\mathrm{S}_{\mathrm{v}}$ | valley slope |
| USGS | USGS regional equations (Waananen and Crippen, 1977) |
| $\beta$-parameters | correspond to log-transformed variables (i.e., $\beta_{1}{ }^{*} \ln \left(\mathrm{~d}_{50}\right), \beta_{2} \ln ^{*}\left(\mathrm{~S}_{\mathrm{v}}{ }^{*} \mathrm{Q}_{2}{ }^{0.5}\right)$ ) |
| $\tau_{*}$ | dimensionless shear stress |
| $\omega$ | specific stream power $=\gamma^{*} \mathrm{~S}^{*} \mathrm{Q}_{i} / \mathrm{W}$ |

Table C. 4 - Summary of bank stability models

| Bank Data | $\beta_{0}$ | Height (m) |  | Angle ( ${ }^{\circ}$ ) |  | Model Performance |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $\beta_{1}{ }^{*}$ | p | $\beta_{2}{ }^{*}$ | p | p | \% Correctly Classified |  |
|  |  |  |  |  |  |  | Unstable | Stable |
| moderate/well-consolidated | 110 | -8.46 | 0.012 | -26.6 | 0.015 | <0.0001 | 94\% | 97\% |
| poor/moderate/well-consolidated | 28.4 | -1.27 | 0.002 | -7.28 | <0.0001 | <0.0001 |  |  |
| confined hillslope | 46.6 | -3.39 | 0.08 | -10.2 | 0.07 | <0.0001 |  |  |

General abbreviations and symbol definitions (excluding units of measure):

| $p$ | probability value |
| :--- | :--- |
| $\beta$-parameters | correspond to log-transformed variables (i.e., $\beta_{1}{ }^{*} \ln ($ height $), \beta_{1}{ }^{*} \ln ($ angle $\left.)\right)$ |

Figure C. 1 - Screening index logistic regression of all grain sizes using HBm1 at $Q_{10}$ vs. $d_{50}$

Figure C. 2 - Specific stream power logistic regression of all grain sizes using HBm1 at $Q_{10}$ vs. $d_{50}$

Figure C. 3 - Dimensionless shear stress logistic regression of all grain sizes using HBm1 at $\mathbf{Q}_{10}$ vs. $d_{50}$

Figure C. 4 - Combined screening index logistic regression of $d_{50}<16 \mathrm{~mm}$ and $d_{50} \geq 16 \mathrm{~mm}$ using HBm1 at $Q_{2}$ vs. $d_{50}$

Figure C. 5 - Risk of bank failure in poorly and moderately-/well-consolidated materials

Figure C. 6 - Risk of bank failure in poorly and unconsolidated materials

Figure C. 7 - Risk of minor mass wasting in hillslope if channel directly connected to hillslope (i.e., confined)

Table C. 5 - Incising and braiding data

| General abbreviations and symbol definitions (excluding units of measure): |  |  |  |
| :---: | :--- | :--- | :--- |
| CEM | Channel Evolution Model | MW | mass wasting |
| conc | concrete | N/A | not applicable |
| constrct | constructed | TRIB | tributary |
| DS | downstream | US | upstream |
| ID | identification | veg | vegetated |
| mid | middle | x-sec | cross-section |

## Global stability:

S stable although MW may be present (such as through unconsolidated media or sections of bank), x-section is generally not actively widening, particularly not widening beyond the original banks. M .俍 heights even closer or equal to that of stable. Vegetation or confinement may also be playing a significant role in the global stability.
U unstable MW seems more complete and the channel seems to be more actively widening. Furthermore, failure in a bank typically results in a form that remains critically unstable. That is, these banks are so far past the stability threshold that failure does not move them significantly closer to stable form

## Mass wasting:

A absent MW is absent from cross-section and adjacent reach in general
B broken MW is broken (fractured/incomplete), occuring in thin slumps across only parts of the bank (vertically and/or longitudinally). MW seems to be such that it is a local phenomenon of temporary
complete MW is complete, occuring in large failure blocks, such that the post-failure geometry remains in a critically unstable state. Provided the stream does not 'fill' the channel back in and reach a

## Fluvial significant: <br> FF fluvial factor direct fluvial bank erosion is a significant factor in the cause of instability.

NF no fluvial fluvial erosion is not a significant factor (although it may be present)
Consolidation:

| MC | moderately or well consolidated | bank appears moderately to well consolidated |
| :--- | :--- | :--- |
| PC | poorly consolidated | bank seems poorly consolidated. This includes banks that may be composed of historic channel beds; however, they show at least some consolidation (that is, they |

UC unconsolidated
bank seems poorly consolidated. This includes banks that may be composed of historic channel beds; however, they show at least some consolidation (that is, they ypically have had a chance to begin to consolidate such that they don't fail at the angle of repose of sand)
material that until recently (<10yrs) was the channel bed. Although in the form of a bank, it shows no real consolidation and fails at angles of the angle of repose of sand $\sim 300$.

Confinement:

| HC | hillsilope confined | the measured height and angle is that of a hillslope which confines the channel and restricts its overall ability to significantly wident |
| :--- | :--- | :--- |
| BC | boulder or bedrock confined | the measured height and angle is that of a boulder or exposed bedrock which is confining the channel and restricting its overall ability to widen |
| UC | unconfined | the measured bank height and angle being rated is not directly confined by hillslope, boulder, or bedrock |

Dominant vegetation (extent + type): extent:
dominant type:

| A | absent | vegetation at cross-section is absent from both the tops and slopes of banks |
| :---: | :--- | :--- |
| B | burned | vegetation was recently burned and has not recovered to pre-fire state |
| F | fragmented | vegetation is present but fragmented at cross section |
| T | thick | vegetation is thick and likely playing a significant role in slope stability |
| C | chaparral | stereotypical Chaparral of southern California - generally dry and shrubby |
| T | temperate trees and grasses | temperate species such as grasses and trees |
| H | hydrophilic | hydrophilic species that occur only in regularly moist soils |
| E | embanked | embanked (although not riprap, typically more intended or permanent than fill soil) |
| F | fill | fill (fill soil with little compaction or consolidation) |
| G | graded | graded but appears to be cut into original floodplain rather than fill |
| R | riprap | riprap |
| N | none | no artificial material affecting current bank stability |

| General abbreviations and symbol definitions (excluding units of measure): |  |  |  |
| :---: | :--- | :--- | :--- |
| CEM | Channel Evolution Model | MW | mass wasting |
| conc | concrete | N/A | not applicable |
| constrct | constructed | TRIB | tributary |
| DS | downstream | US | upstream |
| ID | identification | veg | vegetated |
| mid | middle | x-sec | cross-section |

## Global stability:

S stable although MW may be present (such as through unconsolidated media or sections of bank), x-section is generally not actively widening, particularly not widening beyond the original banks. M .俍 heights even closer or equal to that of stable. Vegetation or confinement may also be playing a significant role in the global stability.
U unstable MW seems more complete and the channel seems to be more actively widening. Furthermore, failure in a bank typically results in a form that remains critically unstable. That is, these banks are so far past the stability threshold that failure does not move them significantly closer to stable form

## Mass wasting:

A absent MW is absent from cross-section and adjacent reach in general
B broken MW is broken (fractured/incomplete), occuring in thin slumps across only parts of the bank (vertically and/or longitudinally). MW seems to be such that it is a local phenomenon of temporary
complete MW is complete, occuring in large failure blocks, such that the post-failure geometry remains in a critically unstable state. Provided the stream does not 'fill' the channel back in and reach a

## Fluvial significant: <br> FF fluvial factor direct fluvial bank erosion is a significant factor in the cause of instability.

NF no fluvial fluvial erosion is not a significant factor (although it may be present)
Consolidation:

| MC | moderately or well consolidated | bank appears moderately to well consolidated |
| :--- | :--- | :--- |
| PC | poorly consolidated | bank seems poorly consolidated. This includes banks that may be composed of historic channel beds; however, they show at least some consolidation (that is, they |

UC unconsolidated
bank seems poorly consolidated. This includes banks that may be composed of historic channel beds; however, they show at least some consolidation (that is, they ypically have had a chance to begin to consolidate such that they don't fail at the angle of repose of sand)
material that until recently (<10yrs) was the channel bed. Although in the form of a bank, it shows no real consolidation and fails at angles of the angle of repose of sand $\sim 300$.

Confinement:

| HC | hillsilope confined | the measured height and angle is that of a hillslope which confines the channel and restricts its overall ability to significantly wident |
| :--- | :--- | :--- |
| BC | boulder or bedrock confined | the measured height and angle is that of a boulder or exposed bedrock which is confining the channel and restricting its overall ability to widen |
| UC | unconfined | the measured bank height and angle being rated is not directly confined by hillslope, boulder, or bedrock |

Dominant vegetation (extent + type): extent:
dominant type:

| A | absent | vegetation at cross-section is absent from both the tops and slopes of banks |
| :---: | :--- | :--- |
| B | burned | vegetation was recently burned and has not recovered to pre-fire state |
| F | fragmented | vegetation is present but fragmented at cross section |
| T | thick | vegetation is thick and likely playing a significant role in slope stability |
| C | chaparral | stereotypical Chaparral of southern California - generally dry and shrubby |
| T | temperate trees and grasses | temperate species such as grasses and trees |
| H | hydrophilic | hydrophilic species that occur only in regularly moist soils |
| E | embanked | embanked (although not riprap, typically more intended or permanent than fill soil) |
| F | fill | fill (fill soil with little compaction or consolidation) |
| G | graded | graded but appears to be cut into original floodplain rather than fill |
| R | riprap | riprap |
| N | none | no artificial material affecting current bank stability |

| General abbreviations and symbol definitions (excluding units of measure): |  |  |  |
| :---: | :--- | :--- | :--- |
| CEM | Channel Evolution Model | MW | mass wasting |
| conc | concrete | N/A | not applicable |
| constrct | constructed | TRIB | tributary |
| DS | downstream | US | upstream |
| ID | identification | veg | vegetated |
| mid | middle | x-sec | cross-section |

## Global stability:

S stable although MW may be present (such as through unconsolidated media or sections of bank), x-section is generally not actively widening, particularly not widening beyond the original banks. M .俍 heights even closer or equal to that of stable. Vegetation or confinement may also be playing a significant role in the global stability.
U unstable MW seems more complete and the channel seems to be more actively widening. Furthermore, failure in a bank typically results in a form that remains critically unstable. That is, these banks are so far past the stability threshold that failure does not move them significantly closer to stable form

## Mass wasting:

A absent MW is absent from cross-section and adjacent reach in general
B broken MW is broken (fractured/incomplete), occuring in thin slumps across only parts of the bank (vertically and/or longitudinally). MW seems to be such that it is a local phenomenon of temporary
complete MW is complete, occuring in large failure blocks, such that the post-failure geometry remains in a critically unstable state. Provided the stream does not 'fill' the channel back in and reach a

## Fluvial significant: <br> FF fluvial factor direct fluvial bank erosion is a significant factor in the cause of instability.

NF no fluvial fluvial erosion is not a significant factor (although it may be present)
Consolidation:

| MC | moderately or well consolidated | bank appears moderately to well consolidated |
| :--- | :--- | :--- |
| PC | poorly consolidated | bank seems poorly consolidated. This includes banks that may be composed of historic channel beds; however, they show at least some consolidation (that is, they |

UC unconsolidated
bank seems poorly consolidated. This includes banks that may be composed of historic channel beds; however, they show at least some consolidation (that is, they ypically have had a chance to begin to consolidate such that they don't fail at the angle of repose of sand)
material that until recently (<10yrs) was the channel bed. Although in the form of a bank, it shows no real consolidation and fails at angles of the angle of repose of sand $\sim 300$.

Confinement:

| HC | hillsilope confined | the measured height and angle is that of a hillslope which confines the channel and restricts its overall ability to significantly wident |
| :--- | :--- | :--- |
| BC | boulder or bedrock confined | the measured height and angle is that of a boulder or exposed bedrock which is confining the channel and restricting its overall ability to widen |
| UC | unconfined | the measured bank height and angle being rated is not directly confined by hillslope, boulder, or bedrock |

Dominant vegetation (extent + type): extent:
dominant type:

| A | absent | vegetation at cross-section is absent from both the tops and slopes of banks |
| :---: | :--- | :--- |
| B | burned | vegetation was recently burned and has not recovered to pre-fire state |
| F | fragmented | vegetation is present but fragmented at cross section |
| T | thick | vegetation is thick and likely playing a significant role in slope stability |
| C | chaparral | stereotypical Chaparral of southern California - generally dry and shrubby |
| T | temperate trees and grasses | temperate species such as grasses and trees |
| H | hydrophilic | hydrophilic species that occur only in regularly moist soils |
| E | embanked | embanked (although not riprap, typically more intended or permanent than fill soil) |
| F | fill | fill (fill soil with little compaction or consolidation) |
| G | graded | graded but appears to be cut into original floodplain rather than fill |
| N | riprap | none |

| General abbreviations and symbol definitions (excluding units of measure): |  |  |  |
| :---: | :--- | :--- | :--- |
| CEM | Channel Evolution Model | MW | mass wasting |
| conc | concrete | N/A | not applicable |
| constrct | constructed | TRIB | tributary |
| DS | downstream | US | upstream |
| ID | identification | veg | vegetated |
| mid | middle | x-sec | cross-section |

## Global stability:

S stable although MW may be present (such as through unconsolidated media or sections of bank), x-section is generally not actively widening, particularly not widening beyond the original banks. MW俍 heights even closer or equal to that of stable. Vegetation or confinement may also be playing a significant role in the global stability.
U unstable MW seems more complete and the channel seems to be more actively widening. Furthermore, failure in a bank typically results in a form that remains critically unstable. That is, these banks are so far past the stability threshold that failure does not move them significantly closer to stable form

## Mass wasting:

A absent MW is absent from cross-section and adjacent reach in general
B broken MW is broken (fractured/incomplete), occuring in thin slumps across only parts of the bank (vertically and/or longitudinally). MW seems to be such that it is a local phenomenon of temporary
complete MW is complete, occuring in large failure blocks, such that the post-failure geometry remains in a critically unstable state. Provided the stream does not 'fill' the channel back in and reach a

## Fluvial significant: <br> FF fluvial factor direct fluvial bank erosion is a significant factor in the cause of instability.

NF no fluvial fluvial erosion is not a significant factor (although it may be present)
Consolidation:

| MC | moderately or well consolidated | bank appears moderately to well consolidated |
| :--- | :--- | :--- |
| PC | poorly consolidated | bank seems poorly consolidated. This includes banks that may be composed of historic channel beds; however, they show at least some consolidation (that is, they <br> typically have had a chance to begin to consolidate such that they don't fail at the angle of repose of sand) |

UC unconsolidated ypically have had a chance to begin to consolidate such that they don't fail at the angle of repose of sand)
material that until recently (<10yrs) was the channel bed. Although in the form of a bank, it shows no real consolidation and fails at angles of the angle of repose of sand ~ 300 .

Confinement:

| HC | hillsilope confined | the measured height and angle is that of a hillslope which confines the channel and restricts its overall ability to significantly wident |
| :--- | :--- | :--- |
| BC | boulder or bedrock confined | the measured height and angle is that of a boulder or exposed bedrock which is confining the channel and restricting its overall ability to widen |
| UC | unconfined | the measured bank height and angle being rated is not directly confined by hillslope, boulder, or bedrock |

Dominant vegetation (extent + type): extent:
dominant type:

| A | absent | vegetation at cross-section is absent from both the tops and slopes of banks |
| :--- | :--- | :--- |
| B | burned | vegetation was recently burned and has not recovered to pre-fire state |
| F | fragmented | vegetation is present but fragmented at cross section |
| T | thick | vegetation is thick and likely playing a significant role in slope stability |
| C | chaparral | stereotypical Chaparral of southern California - generally dry and shrubby |
| T | temperate trees and grasses | temperate species such as grasses and trees |
| H | hydrophilic | hydrophilic species that occur only in regularly moist soils |
| E | embanked | embanked (although not riprap, typically more intended or permanent than fill soil) |
| F | fill | fill (fill soil with little compaction or consolidation) |
| G | graded | graded but appears to be cut into original floodplain rather than fill |
| R | riprap | riprap |
| N | none | no artificial material affecting current bank stability |
